Embedded Time Series Storage: A Cookbook

Andrey Pechkurov

About me

- Java (for a long time) and Node.js (for quite a long time) developer
- Node.js core collaborator
- Interests: web, system architecture, distributed systems, performance
- Can be found here:
  - https://twitter.com/AndreyPechkurov
  - https://github.com/puzpuzpuz
  - https://medium.com/@apechkurov

- Hazelcast IMDG Management Center (MC)
- Monitoring & management application for IMDG clusters
- Supports stand-alone and servlet container deployment
- Self-contained application, i.e. .jar file and Java is everything you need to run MC
- Frontend part is built with TypeScript, React and Redux
- Backend part is built with Java, Spring and IMDG Java client

Agenda

- A quick intro
- The problem
- Considered options
- Decisions made
- Results and plans

A quick intro

Terminology

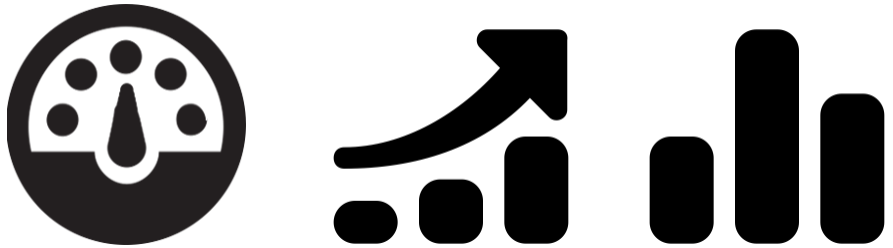
Metric - a numerical value that can be measured at particular time and has a real world meaning. Examples: CPU load, used heap memory. Characterized by name and a set of tags*.

Data point - a metric value measured at the given time. Characterized by metric, timestamp (Unix time) and a value.

* We'll use term "metric" instead of "metric + tags".

Types of metrics

- Gauge (e.g. CPU load, memory consumption)
- Counter (e.g. number of processed operations)
- Histogram (e.g. operation processing latency)



What we mean by "time series"

"Time series" (TS) stand for series of metric data points

```
class DataPoint {

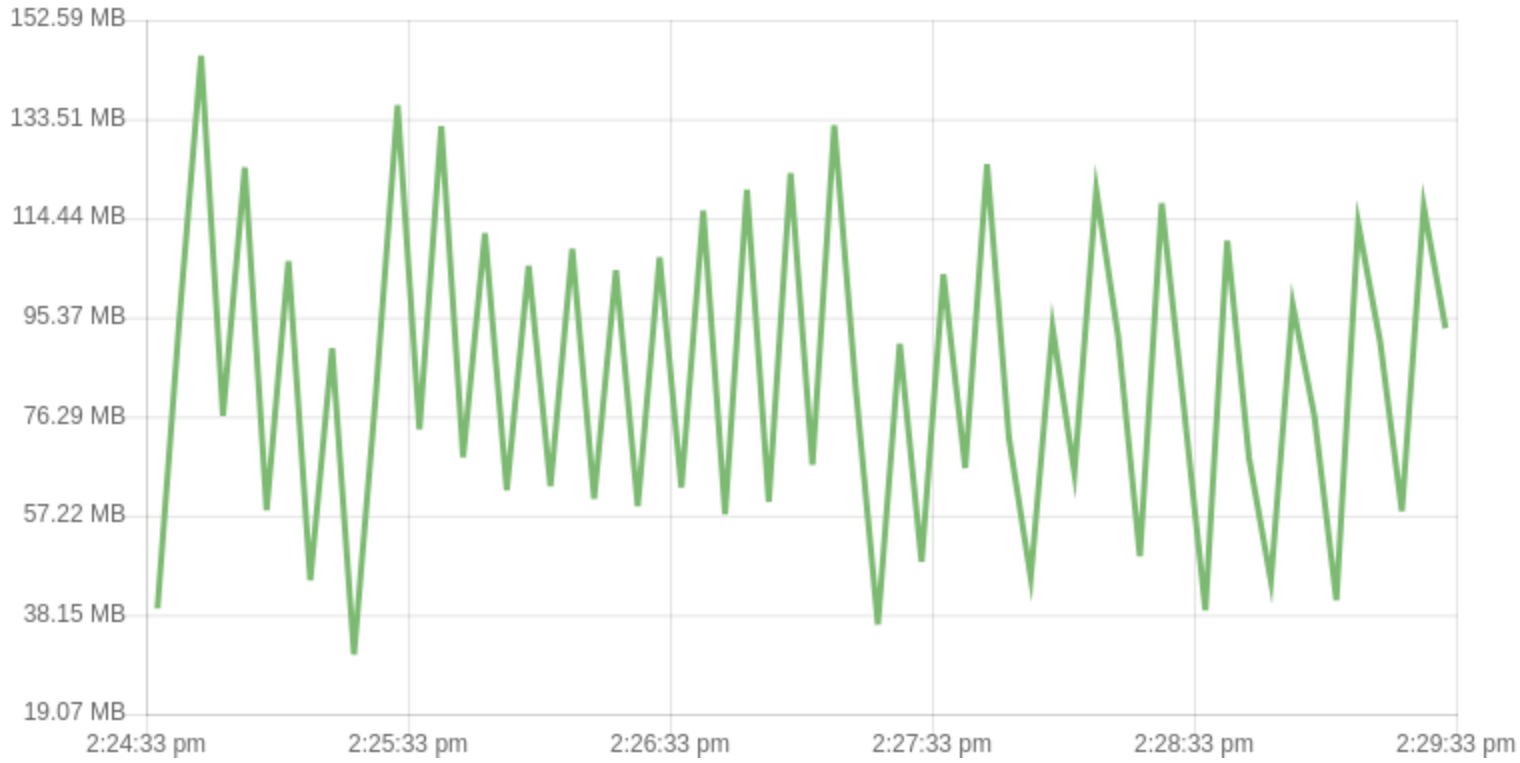
    String metric;
    List<Map.Entry<String, String>> tags;
    long time;
    long value;

}
```

Sample data point

metric	tags	time	value
memory.usedHeap	unit=BYTES	1532689094000	136314880

Sample time series

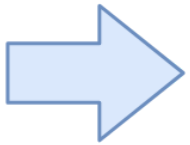


Simple math

10 members
6,000 metrics per each
3 sec interval

Simple math

10 members
6,000 metrics per each
3 sec interval



20K data points per sec
1,728M data points per day
27.6GB of raw data (time + values)

Summary

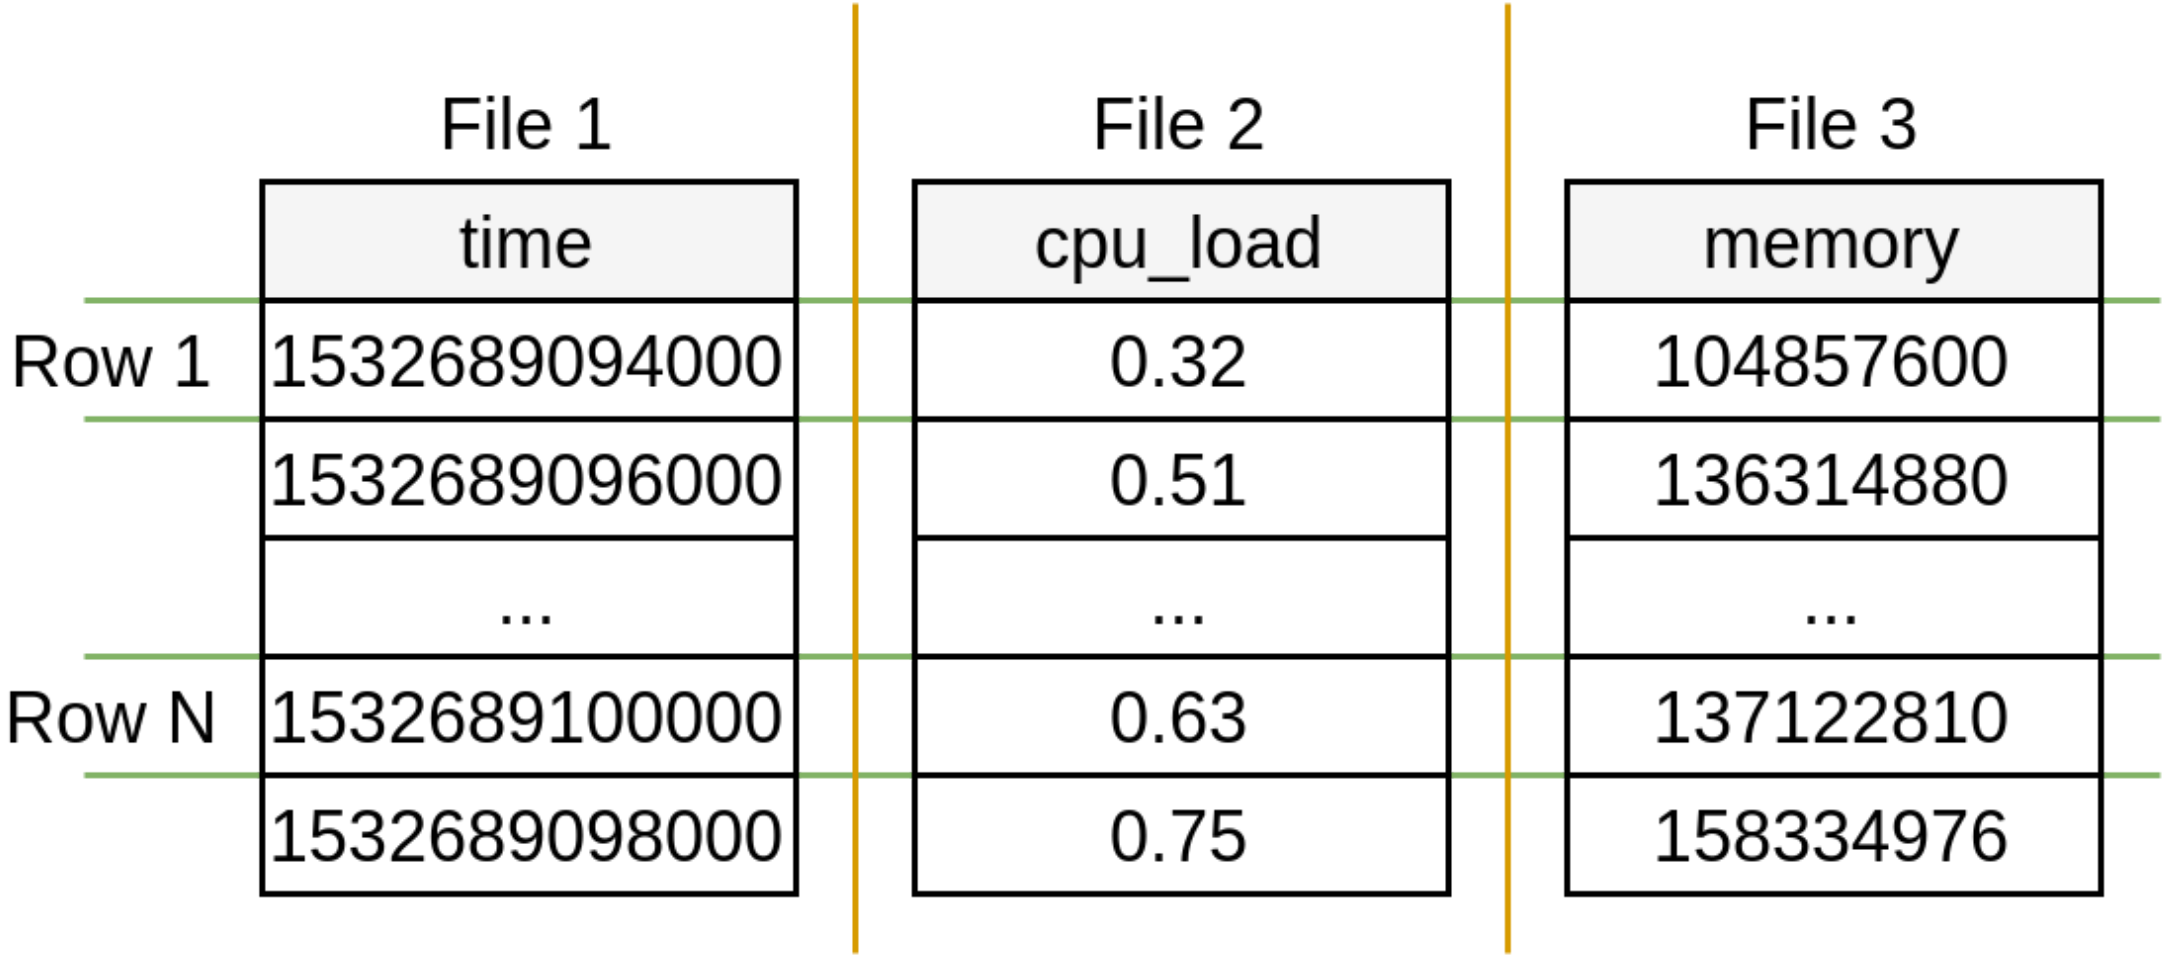
Time series data (usually) implies:

- Lots of writes. Thus, large data volume
- Significantly less reads
- Raw and aggregate queries

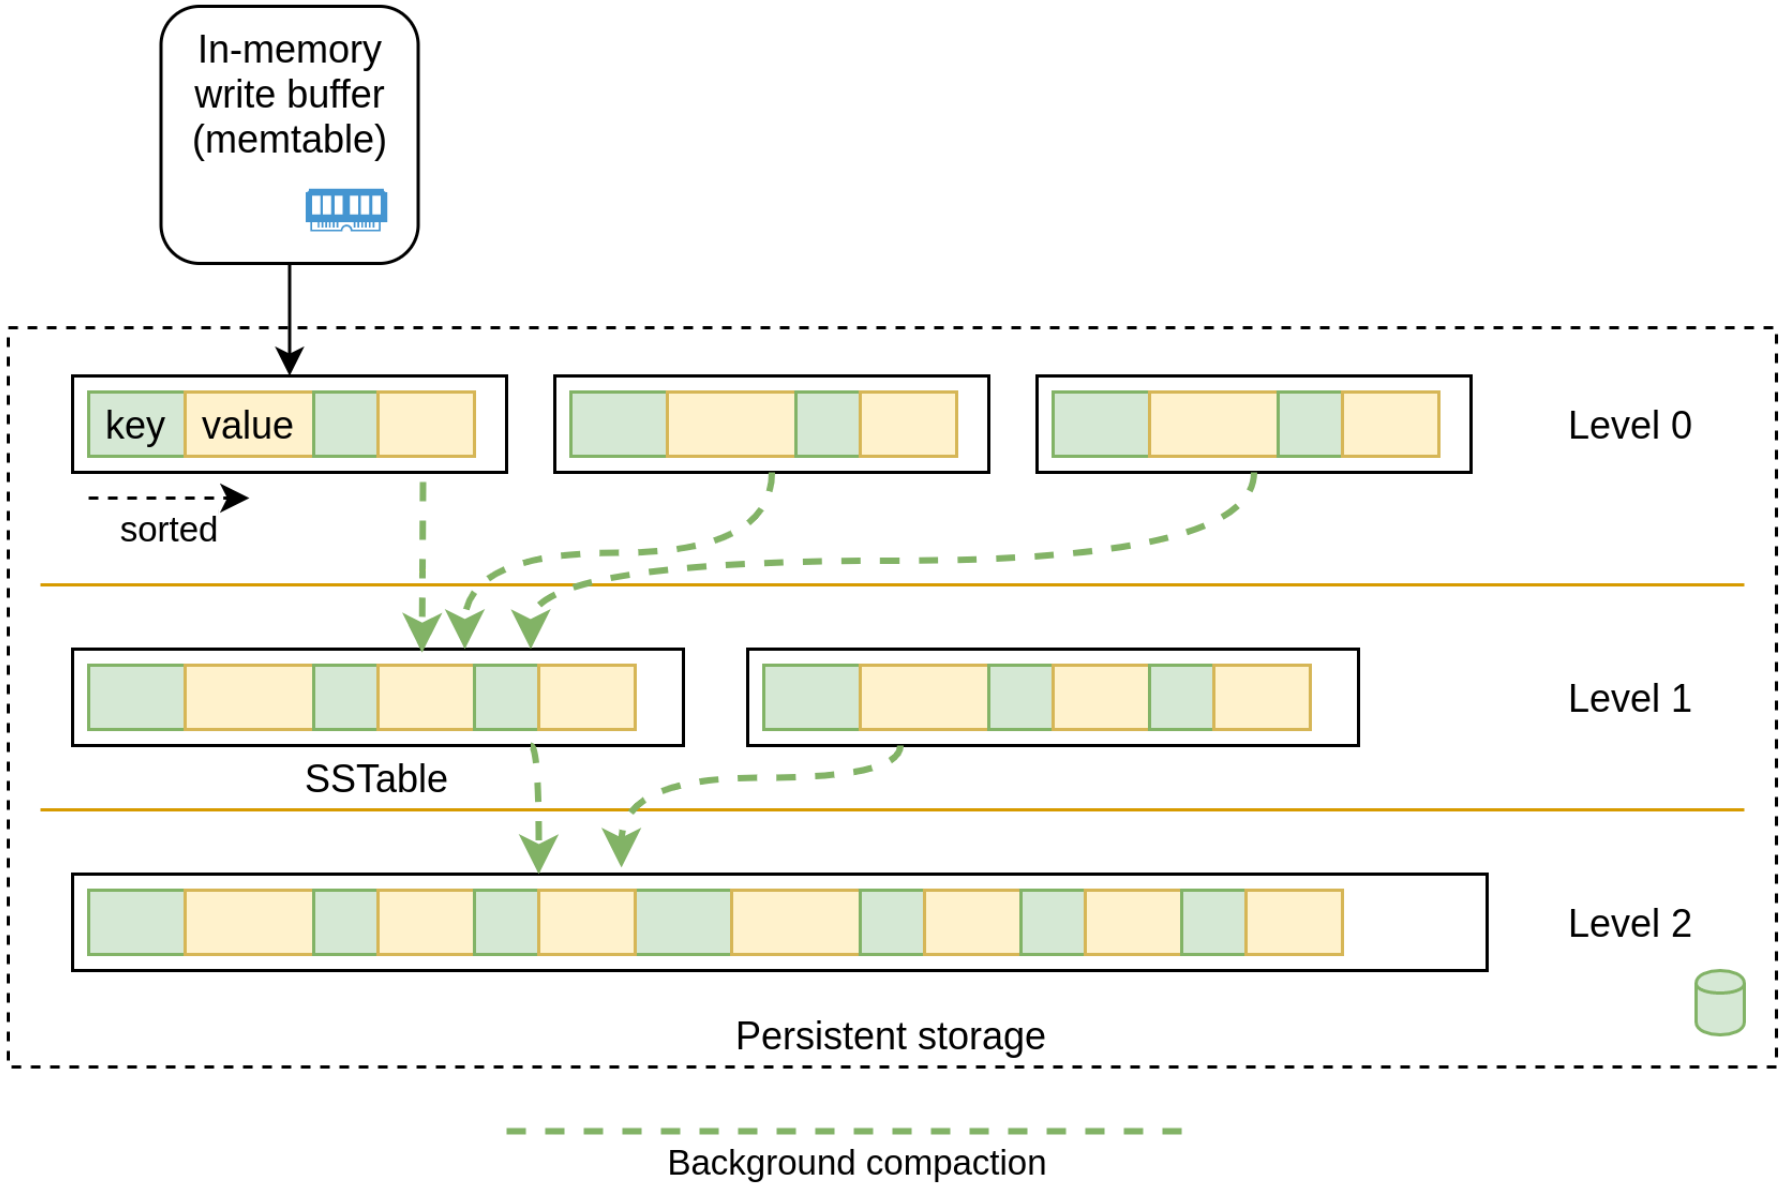
Storage formats

- Column-oriented storage
- Log-structured merge-tree (LSM tree)
- B-tree
- Their variations and combinations

Column-oriented storage



LSM tree



In-memory
write buffer
(memtable)
key
value
sorted
Level 0
Level 1
SSTable
Level 2
Persistent storage
Background compaction

Data compression

- Integer compression
  - Delta encoding
  - Delta-of-delta encoding
  - Simple-8b
  - Run-length encoding
- Floating point compression
  - XOR-based compression
- Type-agnostic compression
  - Dictionary compression
  - Bitmap encoding

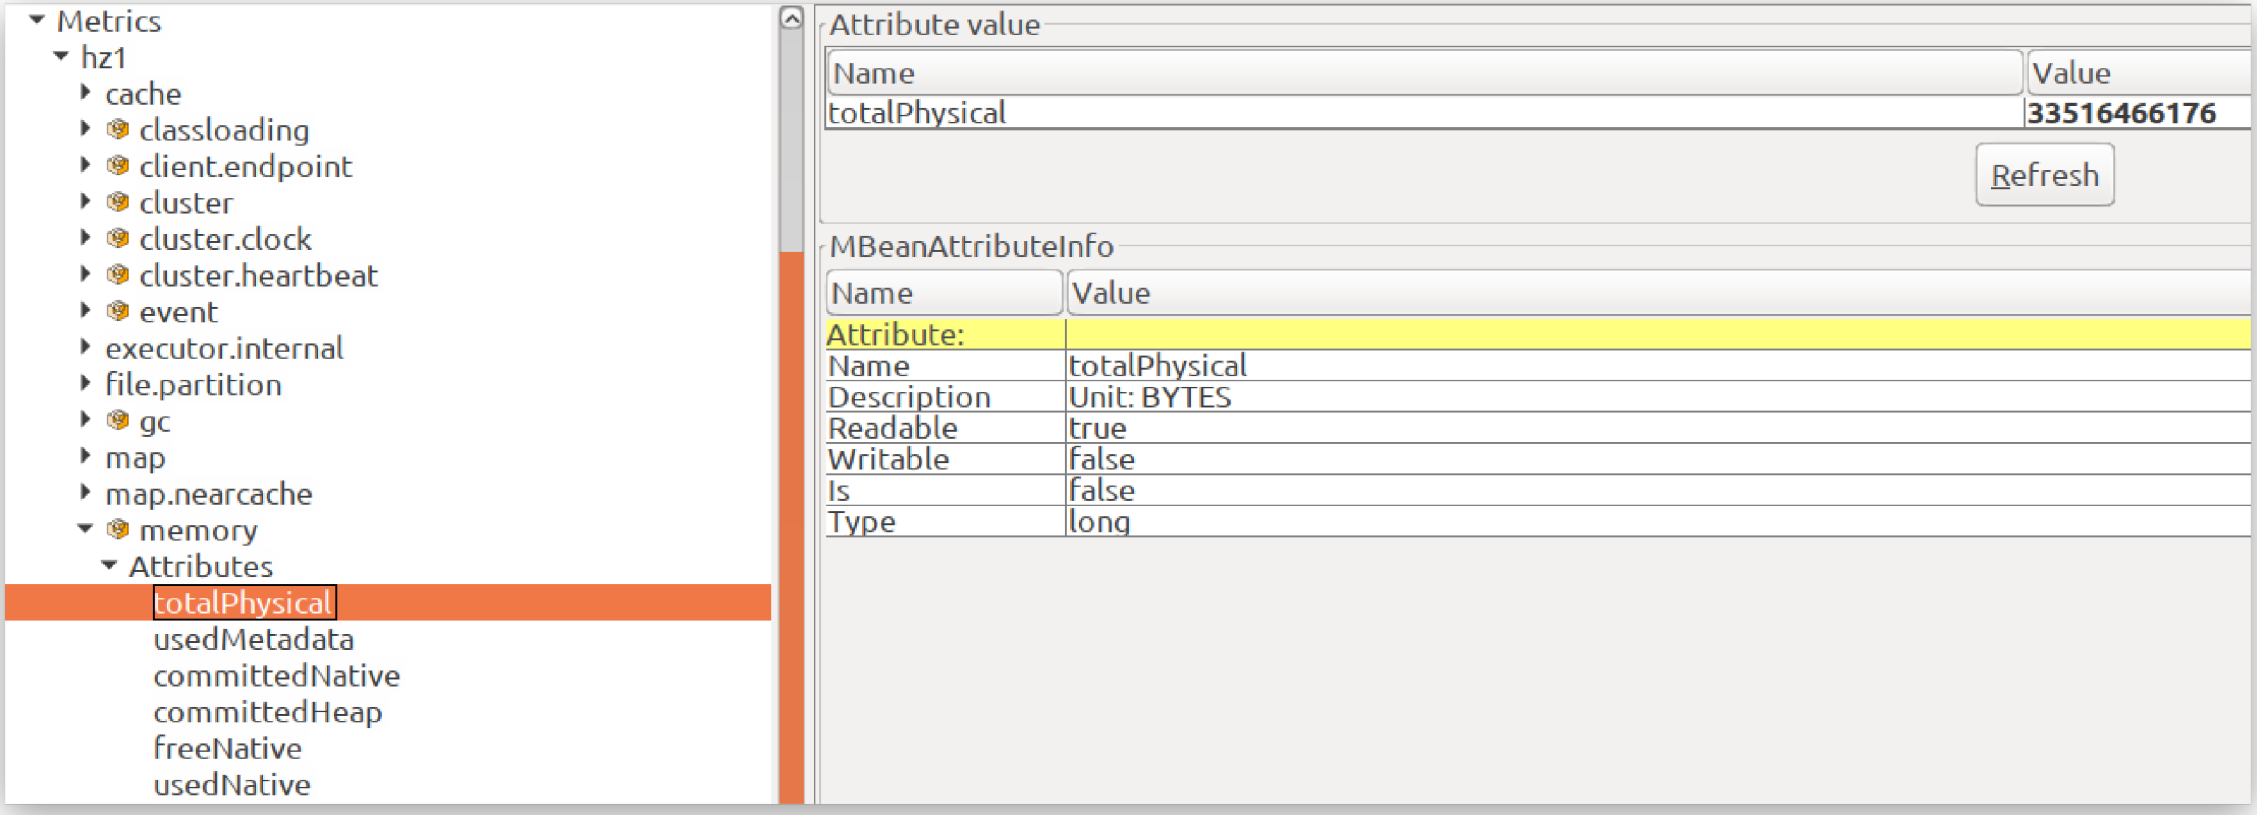
The problem

The problem

- In the past IMDG clusters were reporting their metrics as a large JSON object
- MC was storing collected JSONs into a key-value storage (in-memory and/or JDBM)
- Such approach has some downsides that are critical for us
- Say, it requires changes in many places when we had to add new metrics

The solution

IMDG v4.0+ is capable of reporting collected metrics (probes) to MC in a generic manner



The challenge

- MC has to store those metrics somehow
- Thus, we need a time series database (or, at least, storage)
- Here comes the challenge...

Requirements - must haves

- Embedded time series database or storage
- In-memory and optional persistent modes
- Data compression to achieve low disk footprint in the persistent mode
- Support data retention to avoid running of disk space
- Durability and fault tolerance in the persistent mode

Requirements - nice to haves

- Good write performance (100Ks data points/second on average HW)
- Good enough read performance (10Ks data points/second on average HW)
- Use existing stable SW, when possible

Considered options

TS DBs

- OpenTSDB
- InfluxDB
- TimescaleDB
- Prometheus
- ClickHouse
- and many more

Embedded TS DBs/storages

- Akumuli (C++) - https://akumuli.org
- QuestDB (Java) - https://www.questdb.io

Embedded non-TS DBs/storages

- SQL DBs
  - H2 DB (B-tree)
- Key-value storages
  - H2's MVStore (B-tree)
  - MapDB (HTree, B-tree)
  - RocksDB (LSM tree)

Decisions made

Initial ideas

After initial research and experiments we decided the following:

- Build a TS storage on top of a key-value storage
- Keep the storage API simple

Primitive data layout

key	value
1532689094000@map.totalGetLatency@name=test-map,unit=MS	10234

Draft API

```
public interface MetricsStorage extends AutoCloseable {

    void store(Collection<DataPoint> dataPoints);

    DataPointSeries queryRange(Query query);

    Optional<DataPoint> queryLatest(Query query);

}
```

TODO list

1. Choose one of embedded key-value storages
2. Come up with a way to reduce number of persisted entries
3. Think of sufficient data compression for the persisted data

Item 1: embedded key-value storage

After some experiments we picked up two candidates:

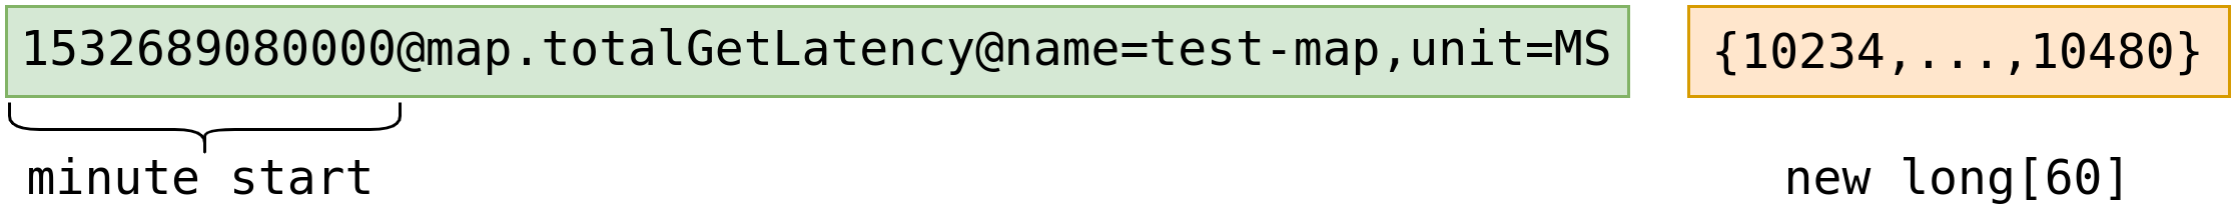
- MapDB (Java)
- RocksDB (C++ with JNI bindings)

RocksDB won the battle in the end.

Item 2: number of persisted entries

- We need to group multiple data points into a single entry somehow
- What if we store data points in buckets? Say, each bucket will contain data points within a minute

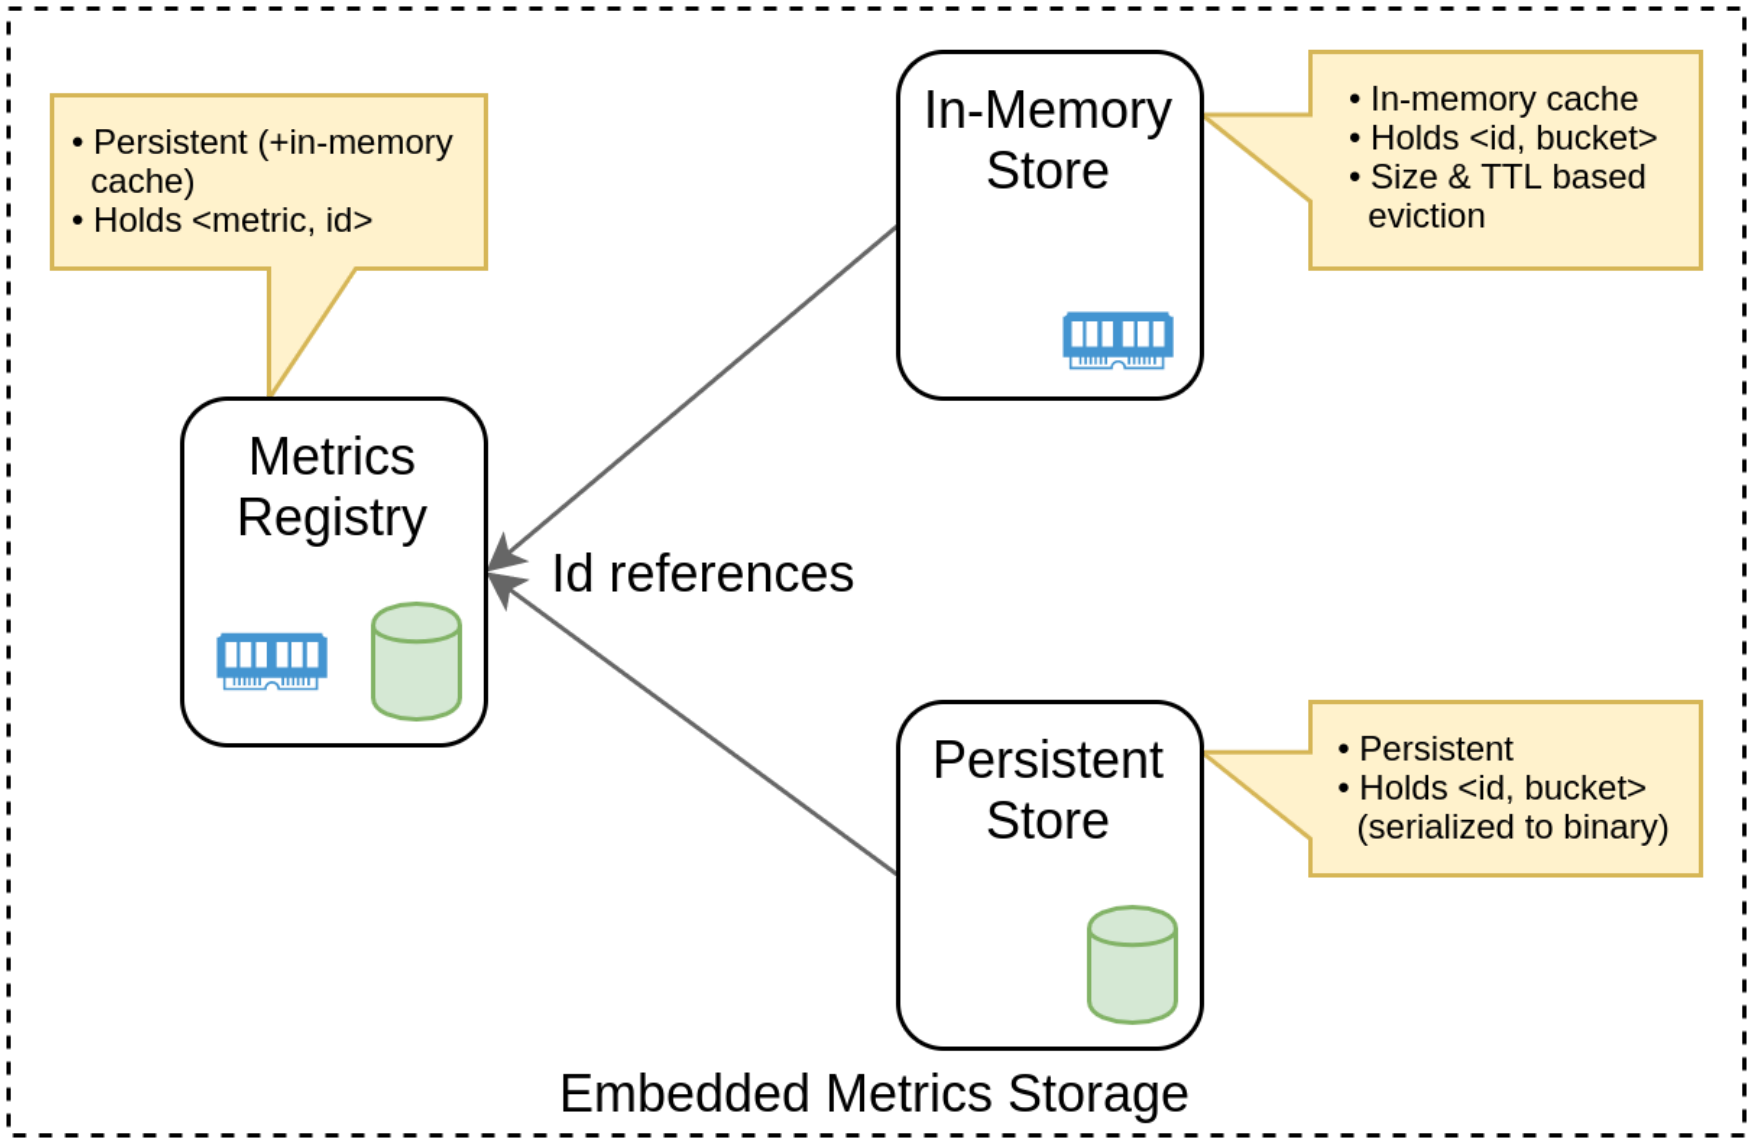
Bucketed data layout



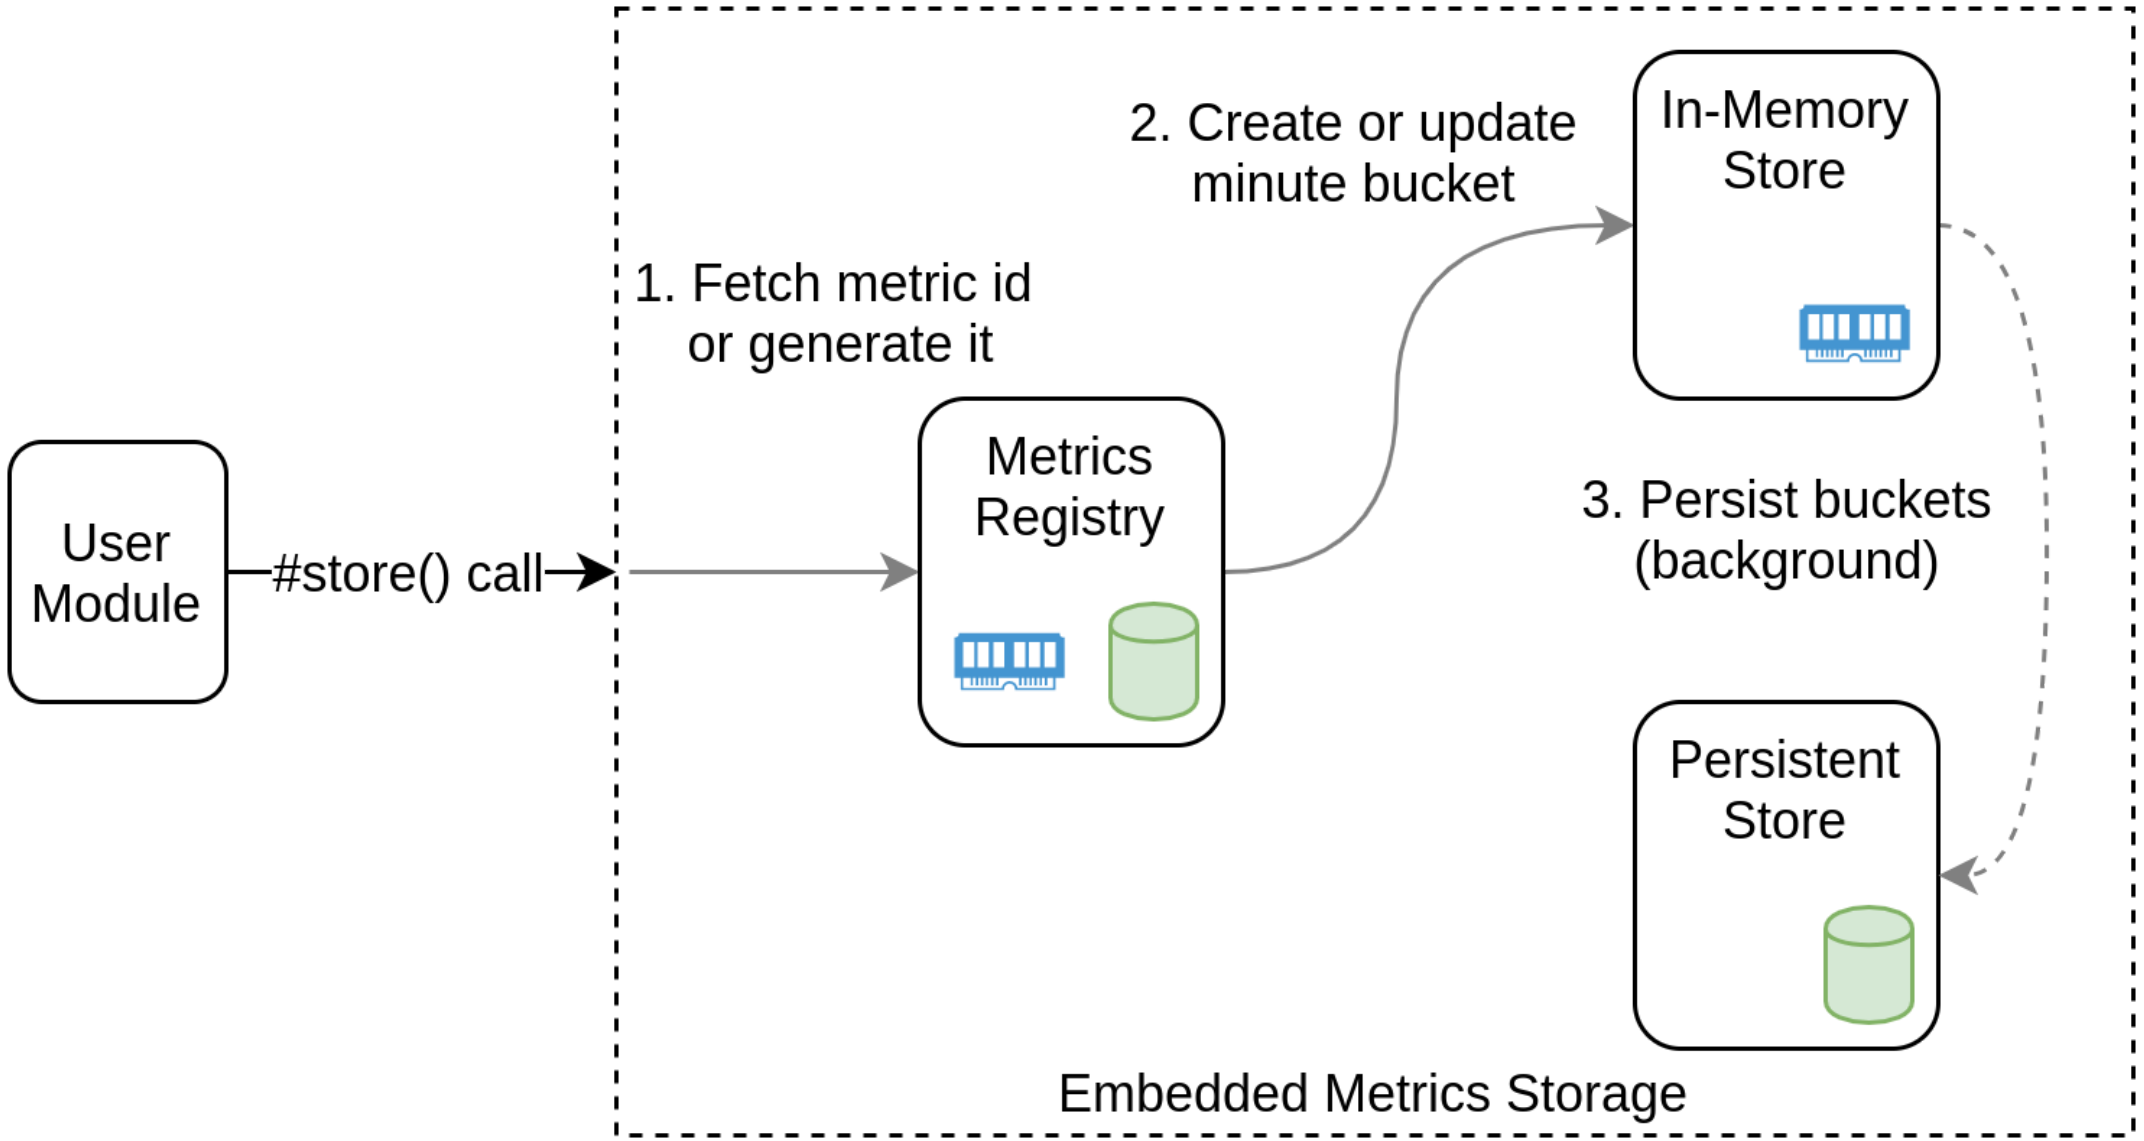
Item 3: data compression

- Keys
  - We could use dictionary compression for metrics
- Values
  - For each minute bucket we could use compression methods for integer numbers, like delta encoding

Overall design

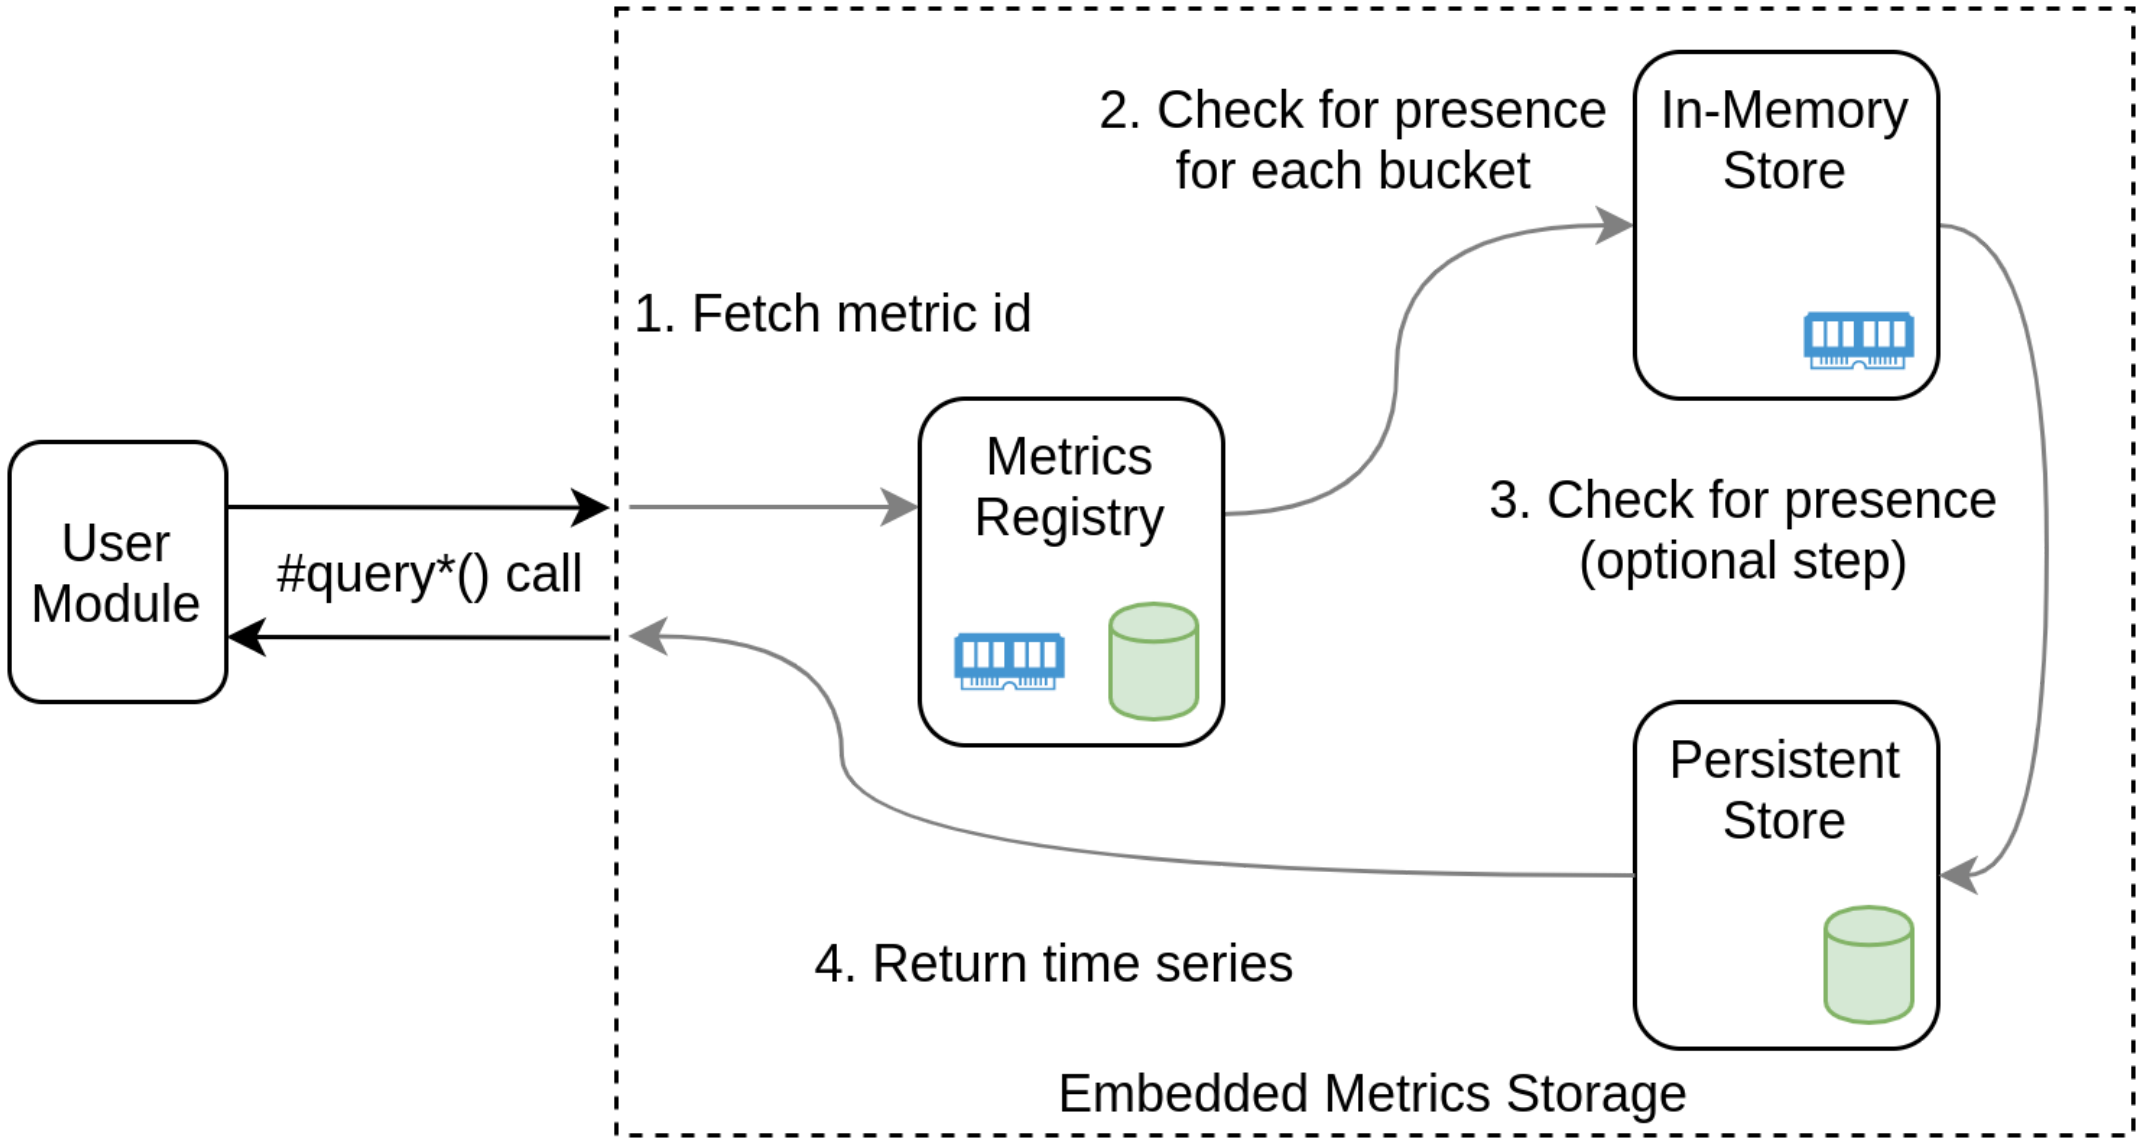


Writes



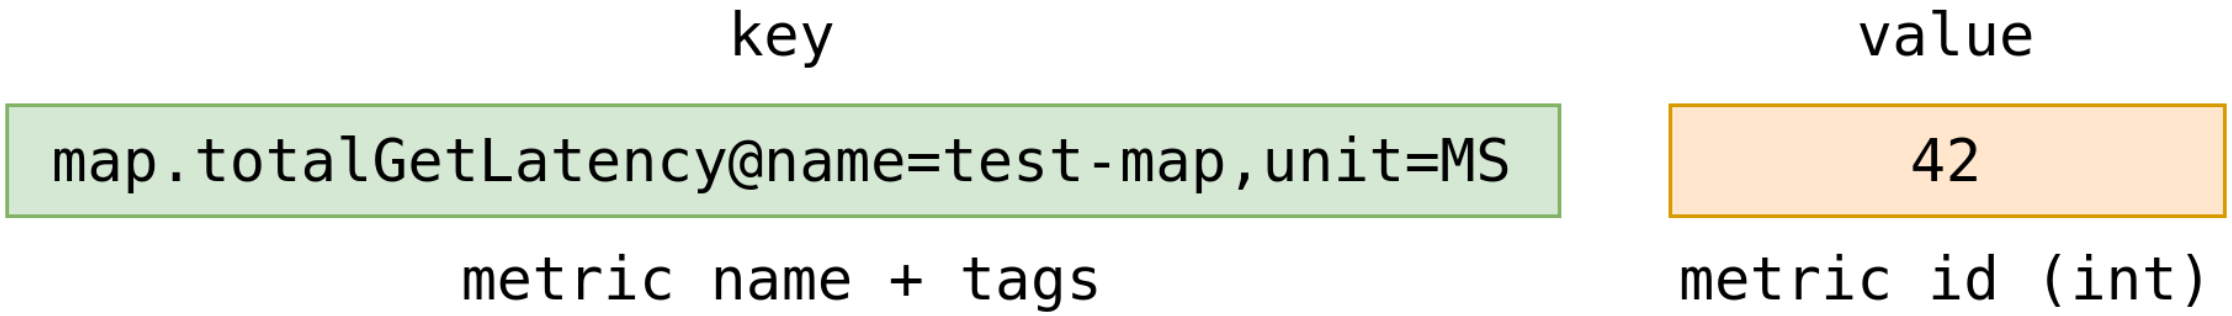
User Module
#store() call
1. Fetch metric id or generate it
Metrics Registry
2. Create or update minute bucket
In-Memory Store
3. Persist buckets (background)
Persistent Store
Embedded Metrics Storage

Reads



2. Check for presence
for each bucket
In-Memory
Store
1. Fetch metric id
Metrics
Registry
User
Module
#query*() call
3. Check for presence
(optional step)
Persistent
Store
4. Return time series
Embedded Metrics Storage

Metrics Registry



Data compression: keys

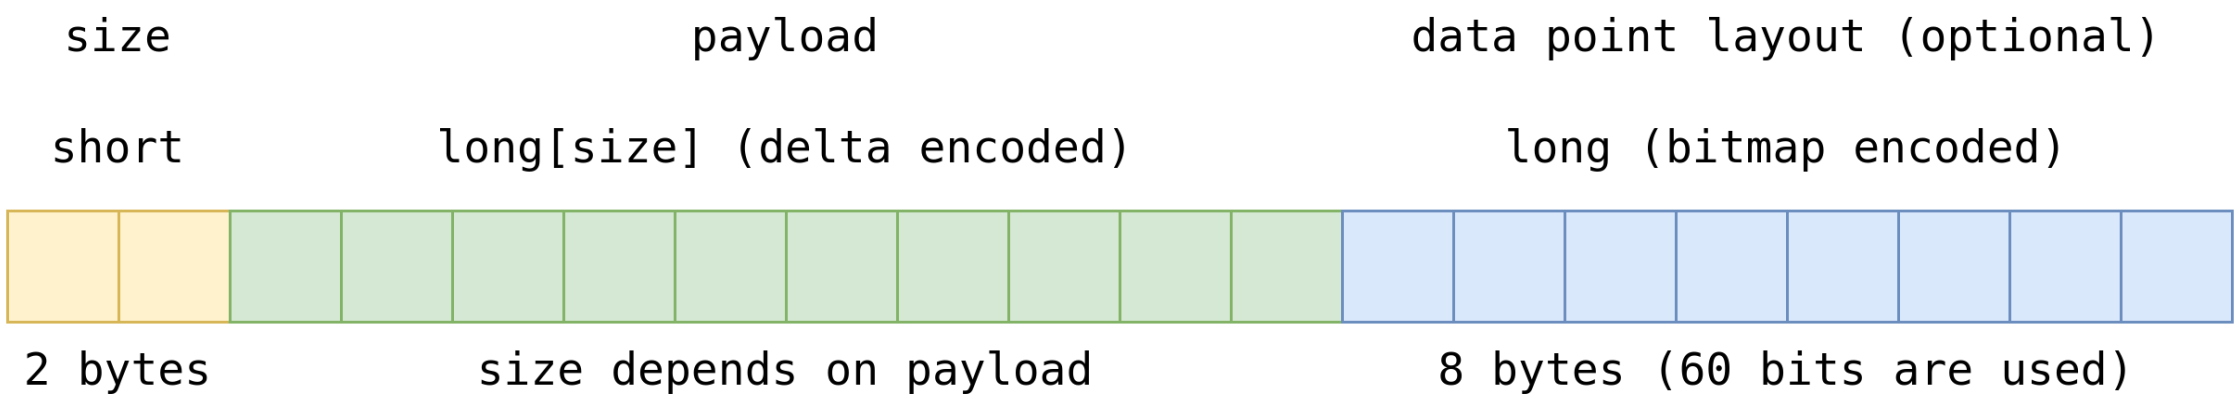
old key format

```
1532689094000@map.totalGetLatency@name=test-map,unit=MS
```

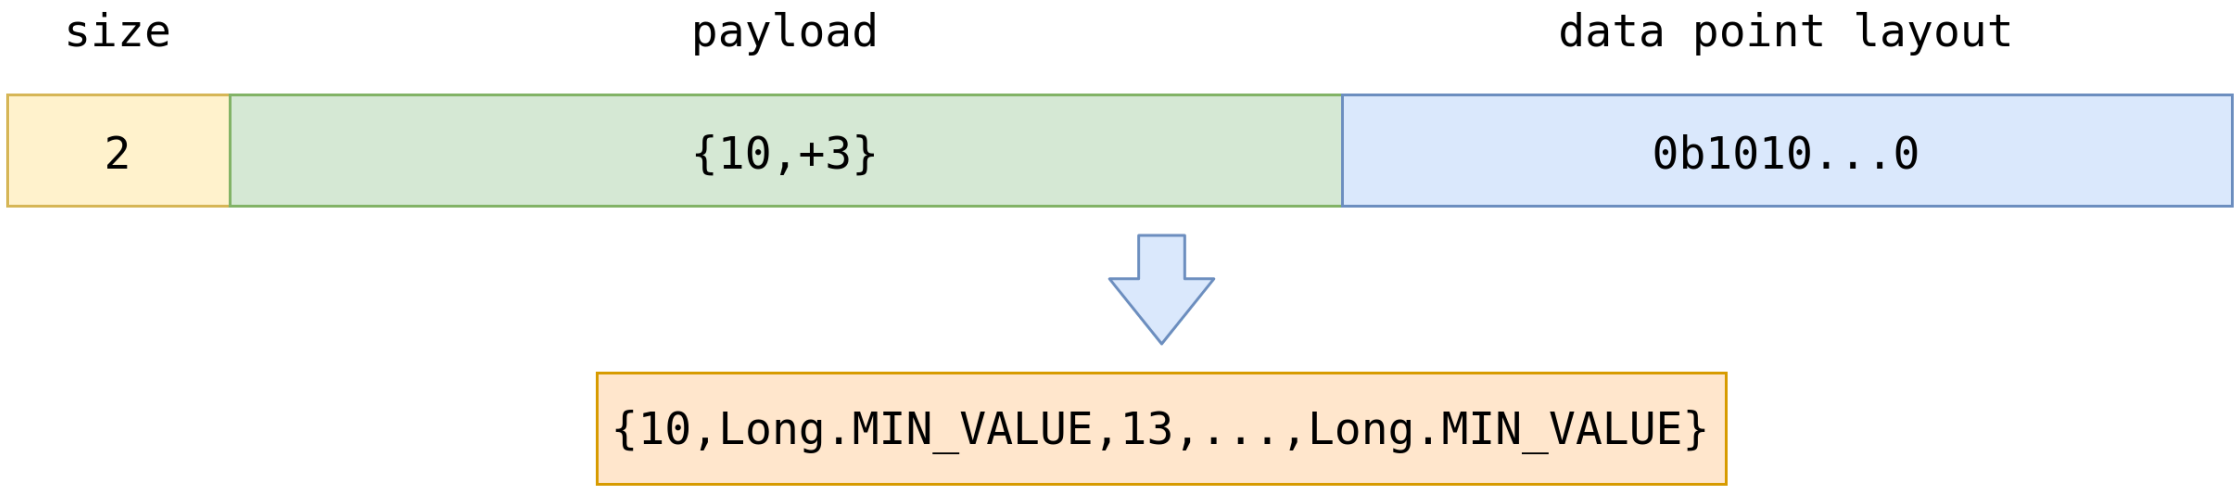
new key format

```
1532689094000@42
```

Data compression: values



Sample compressed value



Value compression efficiency

Scenario	Raw* (bytes)	Delta compressed* (bytes)	Compressed (bytes)	Ratio (vs. Raw)
Const `int` (3 sec)	480	360	13	x37
Random `int` (3 sec)	480	364	156	x3

* `Long.MIN_VALUE` is used to represent missing values

Other features

- Data retention
  - Based on per entry time-to-live (TTL) in RocksDB
- Data durability
  - Pending minute buckets are persisted on graceful shutdown
- Aggregation API
  - Built on top of the storage

Design restrictions

- Insufficient in-memory cache size scenario
  - Potential solution: adapt the size dynamically
- Out of order writes (>1 minute time window)
  - Potential solution: merge buckets during background persistence

Results and plans

Benchmark results

- Scenario:
  - Emulates 10 members, 120,000 metrics, 3 second interval
  - Random values from 0-1000 range
- Results:
  - Writes* - 400K data point/sec
  - Random minute series reads* - 19K ops/sec

* Results were obtained on a laptop

Further plans

- Add support for additional indexes over metrics
- Implement downsampling
- Expose diagnostics information in runtime
- Perform additional testing and optimization

Call to action

- You may want to give a try with IMDG and MC: https://hazelcast.org/
- Open source contributions are welcome as well!

Thank you!
